Trend Study 16C-6-02

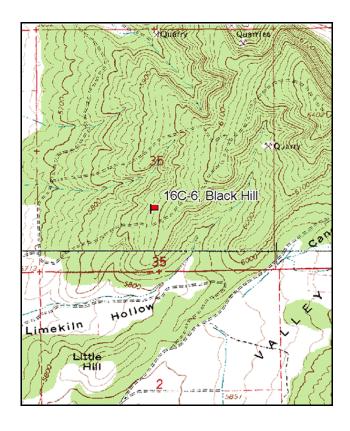

Study site name: Black Hill. Vegetation type: Chained, Seeded P-J.

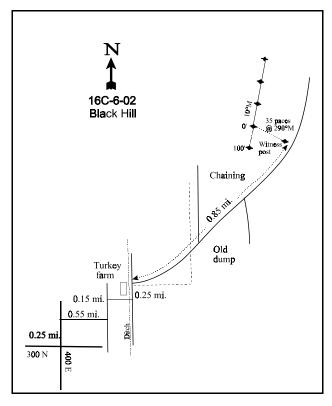

Compass bearing: frequency baseline 190 degrees magnetic.

Frequency belt placement: line 1 (11 & 95ft), line 2 (34ft), line 3 (59ft), line 4 (71ft). Rebar: belt 3 on 2ft.

LOCATION DESCRIPTION

From the intersection of 300 North and 400 East in Ephraim, go north on 400 East for 0.25 miles. Just before the white brick home, turn east and go 0.55 miles. From here, bear left and then right, going 0.15 miles to where the road crosses the Gobble field ditch on the south side of a turkey pen. Cross the ditch and turn left (north) for 0.25 miles. Turn right here and go 0.85 miles into the chaining where you will come to a 4 foot, green witness post on the west side of the road. Stop here and walk 35 paces westward at 290 degrees magnetic to the 0-foot baseline stake marked by browse tag # 427.

DISCUSSION

Black Hill - Trend Study No. 16C-6

The Black Hill study is located on a chained and seeded juniper site northeast of Ephraim. The site is located on Division land above several turkey farms, pastures, and alfalfa fields. The Black Hills drop sharply down to Cane Valley on the east, but slope moderately to the west. The site is on a 16%, west facing slope at an elevation of 6,075 feet. In 1987, a chain was used to mechanically eliminate the juniper on the site. The site was also seeded as part of the treatment. The area was previously characterized as an open stand of juniper with a sparse understory of black sagebrush in association with cheatgrass. Patches of juniper were left on the ridge for cover and travel corridors for big game. Most of the big game use on this site comes from wintering deer. Pellet group transect data taken in 2002 estimated moderate deer use of 66 deer days use/acre (164 ddu/ha) and light elk use at 13 elk days use/acre (33 edu/ha). Livestock also graze the area during the summer. Cow use was estimated at 11 days use/acre (27 cdu/ha) in 2002.

This site is limited by the more shallow soils and lower annual precipitation compared to the nearby Cane Valley study. The soil is described as Amtoft flaggy loam which characteristically are 12-18 inches deep over limestone. Therefore, the root zone may be somewhat restricted. Effective rooting depth at the site was estimated at about 10 inches. Soil textural analysis indicates a clay loam with a neutral to slightly alkaline reactivity (pH = 7.3). Erosion hazard is considered moderate, but with appreciable litter buildup and the abundance of seeded grasses, erosion is minimal. Rock and pavement combined cover are moderate at 12% in 2002. Bare soil was also moderate at 18% in 2002, a slight increase from 13% in 1997. The erosion condition class assessment was determined to be stable in 2002.

As with the Cane Valley study, palatable browse is limited on this site. Black sagebrush, Wyoming big sagebrush, four-wing saltbush, and bitterbrush are all present, but only black sagebrush is moderately abundant. Black sagebrush density was estimated at 760 plants/acre in 2002. Reproduction declined in 2002, probably due to drought conditions, but decadence was low at 16%, vigor was mostly normal, and use was moderate. Wyoming big sagebrush density was estimated at 440 plants/acre in 1997, but only 40 plants/acre in 2002. Apparently, most of the plants classified as Wyoming big sagebrush in 1997 were classified as black sage in 2002. The growth form of Wyoming big sagebrush on this site is low and many of the plants displayed characteristics of black sagebrush. It is likely that many of the sagebrush on the site are hybrids between Wyoming big sagebrush and black sage. Total sagebrush density between 1997 and 2002 is nearly unchanged.

The junipers on the ridge surrounding the study have been highlined. Juniper density on the study site was estimated at 77 trees/acre in 2002, a slight increase from 69 trees/acre in 1997. A small proportion of the trees are survivors from the treatment but many were young trees in the 2 to 3 foot size class. Average diameter of juniper was estimated at only 3 inches. Low rabbitbrush is the most common shrub on the study site with a density of about 2,500 plants/acre in 2002. It had very poor vigor in 1989 due to moisture stress, but showed mostly normal vigor in 1997 and 2002.

Perennial grasses, both seeded and native, dominant the vegetative community. Perennial grasses contributed 48% of the total vegetative cover in 1997, increasing to 65% in 2002. Intermediate wheatgrass is the most abundant species significantly increasing in nested frequency in 2002. Crested wheatgrass, Indian ricegrass, and muttongrass are moderately abundant. As a group, perennial grass sum of nested frequency declined by 7% in 2002 with drought conditions. Grasses appeared to have been grazed by cattle prior to sampling in 2002, but with abundant litter and wolfy material on many plants, grazing has not been a problem in the past. Cheatgrass was moderately abundant in 1997 with a nested frequency of 181 (400 maximum) and a quadrat frequency of 61%. In 2002, cheatgrass was sampled in only 20 quadrats and nested frequency declined significantly. The decline in cheatgrass abundance is not unexpected during drought as was the case in 2002.

Forbs, especially perennial species, have not been significant in the understory since the site was established. Annual species were moderately abundant in 1997, but drastically declined in 2002 with drought. Perennial forbs were sampled in only four total quadrats in 2002. Small burnet, a seeded species, was moderately abundant in 1989, but has since disappeared from the site. Bur buttercup is currently ('02) the most abundant forb on the site.

1989 APPARENT TREND ASSESSMENT

This recently treated area has not yet reached its potential, especially with the poor moisture conditions in the years since the treatment. Site potential is limited, and black sagebrush will likely become the predominant browse because of the shallow soils. Grasses and forbs are clearly an important component on this range for spring and fall big game use. Site management objectives should include the increase of the perennial species to more competitively exclude weedy annuals and cheatgrass. Soils appear to be stable to improving with increasing ground cover.

1997 TREND ASSESSMENT

Trend for soil is up. Percent bare soil declined to 13%, and herbaceous cover continues to increase. Cover contributed by herbaceous species is better for protecting soils from high intensity summer storms. The two preferred browse species for this site are black sagebrush and Wyoming big sagebrush which are almost equal in abundance, 420 and 440 plants/acre respectively. The much better sampling design is responsible for the more accurate estimates of sagebrush density. Percent decadence is low and vigor is good. Trend for browse is stable. The herbaceous understory is more difficult to determine because of the abundance of weedy species. The trend for perennial species is improving, but weedy species should be monitored closely for population trends of three species, cheatgrass, pale alyssum, and bur buttercup. These species currently contribute 21% of the total vegetative cover.

TREND ASSESSMENT

soil - up (5) browse - stable (3) herbaceous understory - slightly up (4)

2002 TREND ASSESSMENT

Soil trend is stable. Although percent bare soil increased in 2002, herbaceous vegetation dominates the site. Vegetation and litter cover are well disbursed and effectively limit erosion. The ratio of protective cover (vegetation, litter, and cryptogams) to bare soil remains good at almost 4:1. Trend for browse is stable. In 1997, Wyoming big sagebrush and black sagebrush were estimated at nearly identical densities. In 2002, most of the sagebrush on the site was classified as black sagebrush. Overall sagebrush density is stable, use is moderate, vigor is mostly normal, and decadence is low at 16%. Trend for the herbaceous understory is stable as perennial grasses remain dominant and only slightly decreased in sum of nested frequency in 2002. Intermediate wheatgrass, the most abundant species, significantly increased in 2002.
